

## ABSTRACT

A game apparatus including at least one rebound surface and flexible material dividing the rebound surface into at least two play areas includes a rebound surface mounting frame and a flexible material mounting frame coupled to hold the frames in substantially fixed relationship but allow movement of one frame in relation to the other for stress relief between the frames. At least one cross member supports the flexible material between play areas and reinforces the flexible material mounting frame. The individual play areas are formed by separate preassembled flexible material units that are mounted in the flexible material mounting frame and then secured together to form the individual play areas. The flexible material mounting frame includes walk bars and also supports basket assemblies used in game play.
